## Study Endpoints

### Primary endpoint:

- Between-group difference in percentage change in TH-BMD from baseline to week 50 among participants who received at least one dose of study medication

### Secondary endpoints:

- Between-group differences in percentage change in LS BMD to week 50
- Between-group differences in percentage change in TH and LS BMD at weeks 14 and 26
- To assess the safety and tolerability of oral Alendronate in PWH initiating ART

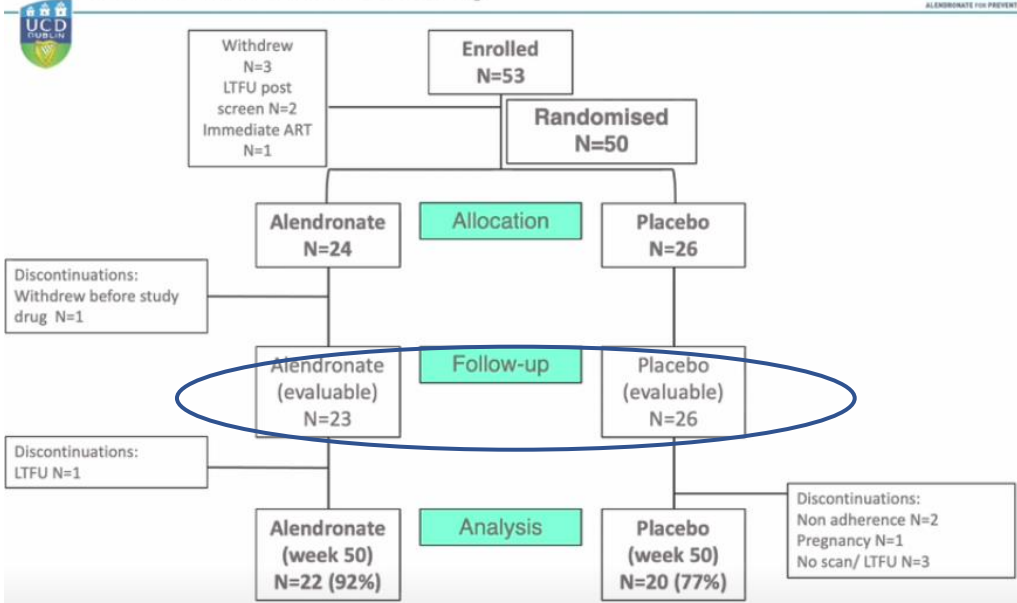

## Inclusion Criteria

- male >25 years old or female >30 years old
- HIV-1 antibody positive (no CD4 or HIV RNA criteria)
- antiretroviral therapy naïve
- eligible for initiation of antiretroviral therapy

## Exclusion Criteria

- history of osteoporosis or fracture
- chronic renal failure
- hypocalcaemia/ hypercalcaemia
- previous treatment/allergy to bisphosphonates
- recent history of any abnormality of the oesophagus
- recent invasive dental work
- recent significant steroid exposure
- pregnancy or breastfeeding

## Enrollment and follow-up

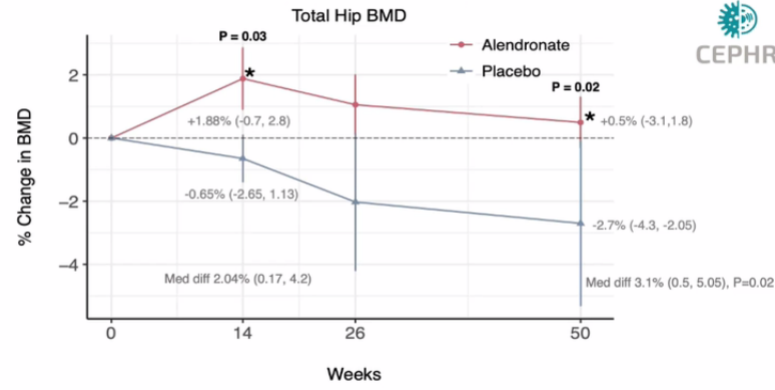

## Baseline Characteristics

|                                  | Overall<br>(N = 50) | Alendronate<br>(N = 24) | Placebo<br>(N = 26) |
|----------------------------------|---------------------|-------------------------|---------------------|
| Age (years)                      | 35 (32, 40)         | 36 (32, 39)             | 34 (31, 41)         |
| Male n (%)                       | 43 (86.0%)          | 20 (83.3%)              | 23 (88.5%)          |

## Percentage change in BMD at Lumbar Spine

|     | 0  | 14 | 26 | 50 |
|-----|----|----|----|----|
| (N) | 24 | 18 | 18 | 22 |
| (N) | 26 | 25 | 23 | 20 |

## Conclusions

- Short course (14 weeks) generic oral Alendronate at ART initiation prevented ART-associated bone loss over 48 weeks at TH
- A protective effect was also observed at the LS but was limited to the first 24 weeks
- Even in PWH on contemporary ART regimes, BMD loss at ART initiation is still evident
- Generic Alendronate is an inexpensive, easily accessible, safe and well tolerated option for preventing bone loss associated with ART initiation – this may be particularly important in resource limited settings
- Further analysis of bone turnover markers and immunological markers may give further mechanistic insights

# SAFETY OF TENOFOVIR ALAFENAMIDE (TAF) IN PATIENTS WITH A HISTORY OF PROXIMAL RENAL TUBULOPATHY ON TDF

Frank A. Post

- Study objective: To assess the safety of TAF in people with HIV who developed treatment-limiting PRT while receiving TDF.
- Hypothesis: TAF exposure in this group of individuals would not result in recurrent PRT and have minimal impact on renal and bone biomarkers.

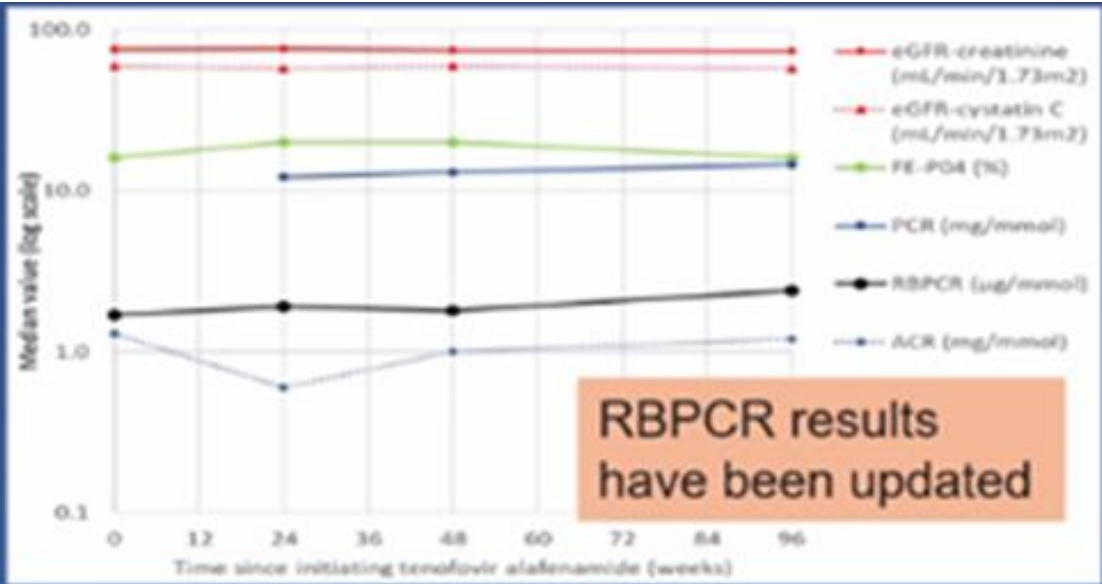

## Methods

- We conducted a multicentre, open-label, single arm switch study (EudraCT: 2016-003345-29)
- We enrolled participants with HIV who experienced treatment-limiting PRT while receiving TDF
  - Histology (acute tubular injury), or  $\geq 2$  of
  - Proteinuria, normoglycaemic glycosuria, hypophosphatemia, rapid eGFR decline
- Participants initiated TAF and were followed up every 12 weeks for 96 weeks; modifications to the ART regimen were allowed
- We analyzed renal and bone biomarkers using multi-level mixed-effects linear regression models

- 31 participants (median age 55 years, 97% male, 87% white)
- All remained on TAF at week 96
- None developed recurrent PRT or Fanconi syndrome

- During 96 weeks of follow up, none of the participants developed recurrent PRT, glycosuria, sustained hypophosphataemia or worsening total proteinuria.
- Additional biomarker analyses showed eGFR-cystatin C, albuminuria, RBPCR, fractional excretion of phosphate, markers of bone turnover and BMD remained stable from baseline.
- These results suggest that TAF is a treatment option for people with HIV who experienced PRT or Fanconi syndrome while taking TDF
- Follow up continues for a further three years to provide additional data for TAF in this population.

# NEUROCOGNITIVO

---

# 12-Year Cognitive Decline is Associated with Lung Disease, Diabetes, and Depression

Scott Letendre, M.D.

## Background

- Cognitive impairment is more common in people with HIV (PWH) than in the general population and is associated with worse quality of life and worse health outcomes.
- Most studies of cognitive change in PWH have focused on decline over a few years but no projects have assessed cognitive change and its correlates over more than a decade in all participants.
- To address this key gap, the 6-site, U.S. CHARTER project reassessed 397 participants 12 years after their initial assessment.

## Methods

- Standardized, comprehensive neuromedical and neuro-cognitive assessments were performed at the initial and 12-year timepoints and included:

- Neuropsychological test battery that assessed 7 cognitive domains
- Medical history & exam, prescribed medications, drug use, and venipuncture.

- The cognitive outcome was regression-based change score (RBCS), which was calculated using normative data from people with and without HIV.

- Decline was defined as change worse than the 5<sup>th</sup> percentile of the normative data.

- Demographic, disease, drug use, and therapy characteristics were analyzed using multivariable regression with  $\alpha=0.15$  for covariate inclusion.

## Participant Characteristics (N=397)

# Graphs of Associations with Global Cognitive Change

Index includes:

- Diabetes @ Visit 2
- Chronic Lung Disease @ Visit 2
- Hypertension @ Visit 1

- Over a median of 12.4 years of follow-up, nearly a quarter of PWH who were on suppressive ART experienced cognitive decline
  - Compared with an estimated 5% of people without HIV
- The magnitude of decline was not severe in most participants and was associated with previously reported aging-related risk factors (e.g., diabetes) as well as with less frequently reported risk factors, such as
  - Chronic Lung Disease
  - Major Depressive Disorder
  - Lifetime Cannabis Use Disorder
- When the CHARTER cohort was first assembled between 2003 and 2007, it was designed to reflect – and generalize to – PWH who receive outpatient healthcare in the U.S. but these 12-year findings may be affected by survivor bias and other biases

# Effects of Switch from 3DR to 2DR on Inflammatory Biomarkers

Sergio Serrano-Villar  
Hospital Universitario Ramón y Cajal  
Madrid, Spain

**Objective:** To assess the effects of switching ART from triple therapy (TT) to 2DR on long-term trajectories of inflammatory markers.

## Methods

Design: Nested study in the Spanish AIDS Cohort (CoRIS)

### Inclusion criteria

- Patients initiating ART in CORIS between 2004-2018 with TT (2NRTI+bPI/INSTI).
- Virological suppression achieved in the first 48 weeks of ART.
- Either remained on TT or switched to 2DR (3TC+bPI, 3TC+DTG, RPV+DTG) or 1DR (LPVr or bDRV).
- At least 3 plasma samples available

### Exclusion criteria

- ART initiation with regimens with <3 drugs
- Virological failure:  $\geq 2$  consecutive viral loads more than 50 copies/mL during the first 48 weeks of ART
- AIDS conditions or serious non-AIDS events (malignancies, cardiovascular disease, end-stage liver disease, end-stage kidney disease), in the first 48 weeks of ART.

From 14,458 patients, 8,416 met these criteria

90 patients on 3DC  
60 patients on 2DC  
30 patients on 1DC

Selected based on  
At least 3 samples  
Longer follow-up

### Statistics

- Plasma samples measured in duplicate using commercial ELISA kits.
- Linear trajectories estimated using piecewise linear mixed models with fixed effects (interaction term biomarker concentration#time, age, sex, risk group, education level, AIDS, CD4 nadir, maximum HIV RNA, biomarker level at HIV RNA suppression).

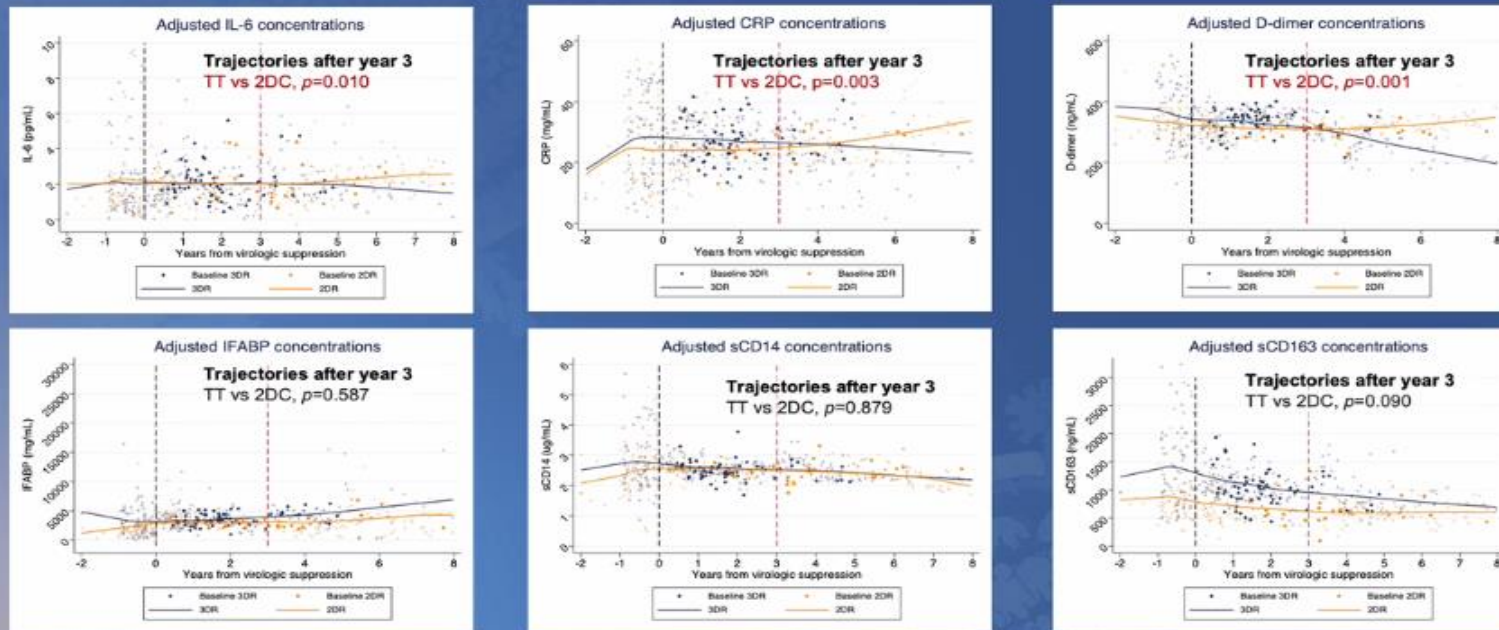

## Results

### General characteristics

|   | TT<br>N=90            | 2DR<br>N=58          | p value |

| Follow-up (years), median (IQR)   | 3.9 (2.5-4.7)         | 5.3 (3.9-6.8)        | <0.001  |

### ART distribution in each group

Baseline: for 3DR represents the second sample after the HIV RNA suppression time point; for 2DR represents the first sample after switch to 2DR. Linear trajectories estimated using **piecewise linear mixed models** with fixed effects (interaction term biomarker concentration\*time, adjusted for age, sex, risk group, education level, AIDS, CD4 nadir, maximum HIV RNA, biomarker level at HIV RNA suppression).

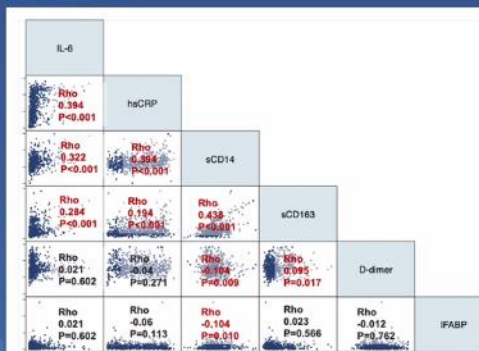

## Results

Multivariate Logistic regression: changes during follow-up TT (ref.) vs. 2DR

Adjusted for age, sex, risk group, education level, AIDS, CD4 nadir, maximum HIV RNA, biomarker level at HIV RNA suppression, years of follow-up

Crossed-correlations between inflammatory biomarkers

## CONCLUSIONS

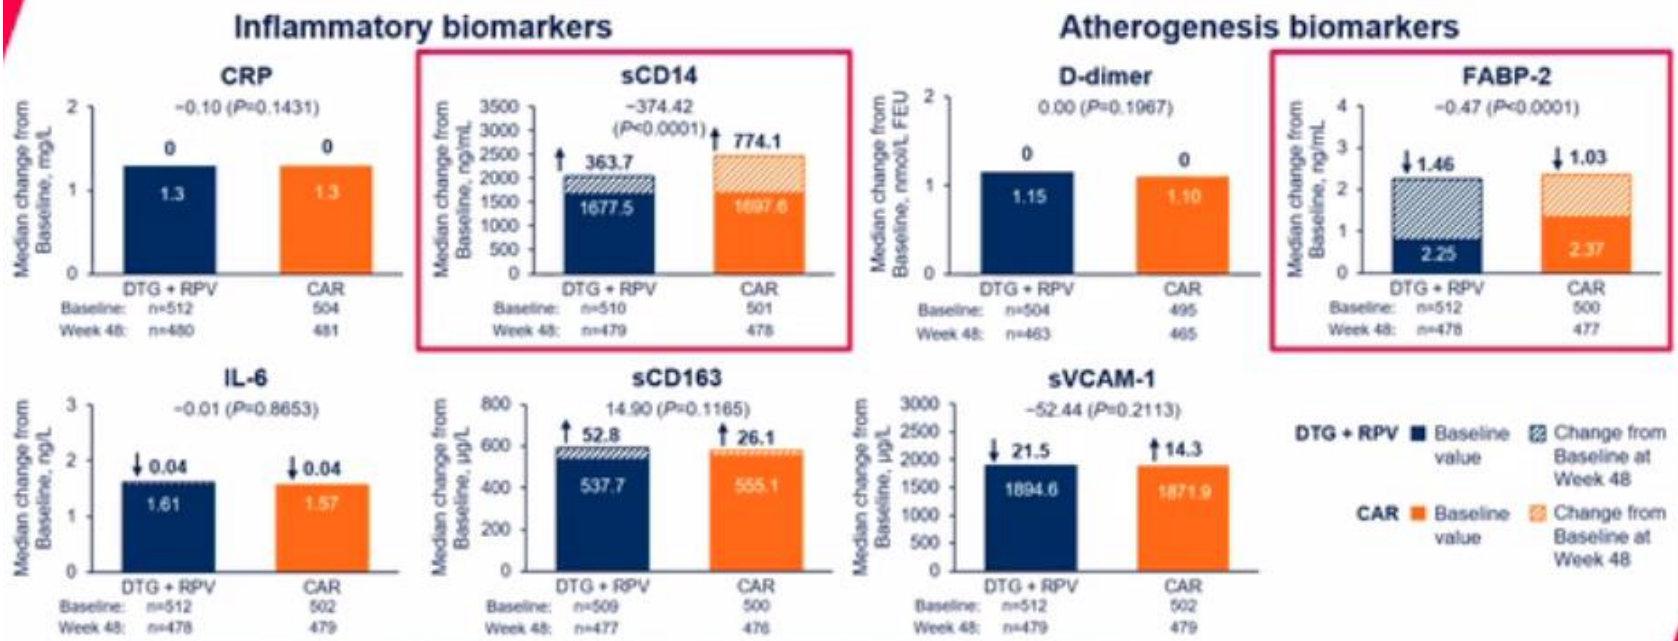

- In this observational study in virally suppressed individuals, maintaining 3DR was associated with a more favourable long-term anti-inflammatory profile than switching to 2DR.
- The potential clinical implications of these findings on the development of non-AIDS events deserve further investigation.

# INFLAMMATORY AND ATHEROGENESIS MARKERS 148 WEEKS POST-SWITCH TO DTG + RPV IN SWORD-1/-2

Josep M. Llibre,<sup>1</sup> Luis Fernando López Cortés,<sup>2</sup> Alicia Aylott,<sup>3</sup> Brian Wynne,<sup>4</sup> Jessica Matthews,<sup>4</sup> Jean van Wyk,<sup>3</sup> Lesley P. Kahn<sup>5</sup>

## Controlled Early-Switch (ES) Phase: Change From Baseline to Week 48 Across Biomarkers

Graphs show pooled data from SWORD-1/2 studies. Median treatment difference (DTG + RPV group - CAR group) and P values on each graph were performed post hoc. CRP, C-reactive protein; FABP-2, fatty acid binding protein 2; IL-6, interleukin 6; s, soluble; VCAM-1, vascular cell adhesion molecule-1.

## No Consistent Pattern of Change in Atherogenesis Biomarkers Was Observed Post-Switch to DTG + RPV Up to Week 148

- The increase in D-dimer was not consistent with the other biomarkers of atherogenesis or across the 2 SWORD studies
- Reductions consistently observed for FABP-2 post-switch across ES and LS groups in SWORD-1 and SWORD-2 suggest no impact on enterocyte integrity and fatty acid metabolism
- Reduction in sVCAM-1 post-switch in SWORD-1 and SWORD-2 but timing differed in ES vs LS groups

ES Baseline Week 48 Week 100 Week 148  
 LS LS Baseline Week 100 Week 148

Plots represent absolute values for each biomarker. Error bars show variance from median or mean value. P values that reached statistical significance for a longitudinal change from Baseline or LS Baseline are indicated with an asterisk.  
 ES, Early Switch; FABP-2, fatty acid binding protein 2; LS, Late Switch; sVCAM-1, soluble vascular cell adhesion molecule-1.

## No Consistent Pattern of Change Across Inflammatory Biomarkers Was Observed Post-Switch to DTG + RPV Up to Week 148

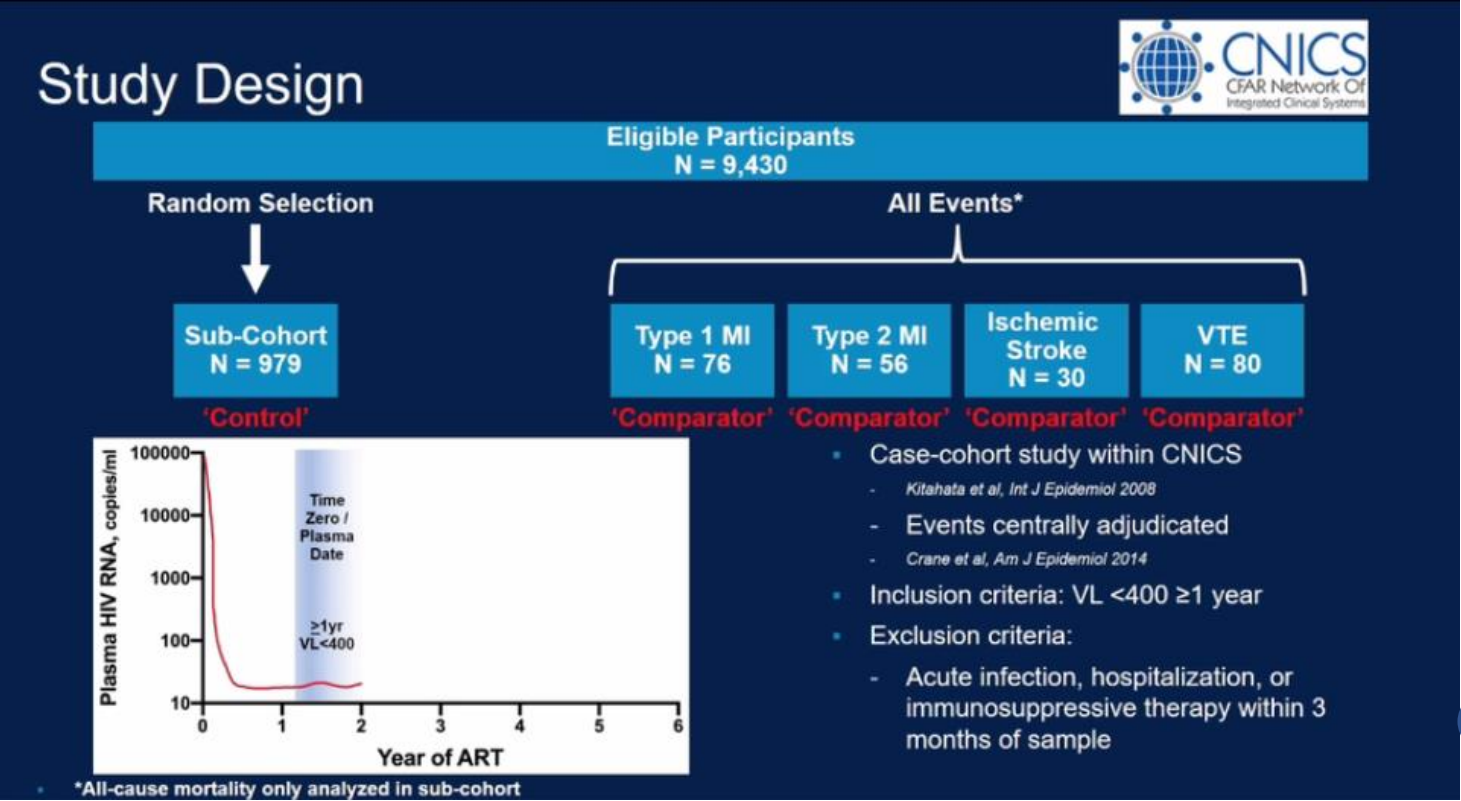

Plots represent absolute values for each biomarker. Error bars show variance from median or mean value. P values that reached statistical significance for a longitudinal change from Baseline or LS Baseline are indicated with an asterisk.  
 CRP, C reactive protein; ES, Early Switch; IL-6, interleukin-6; LS, Late Switch; s, soluble.

ES Baseline Week 48 Week 100 Week 148  
 LS LS Baseline Week 100 Week 148

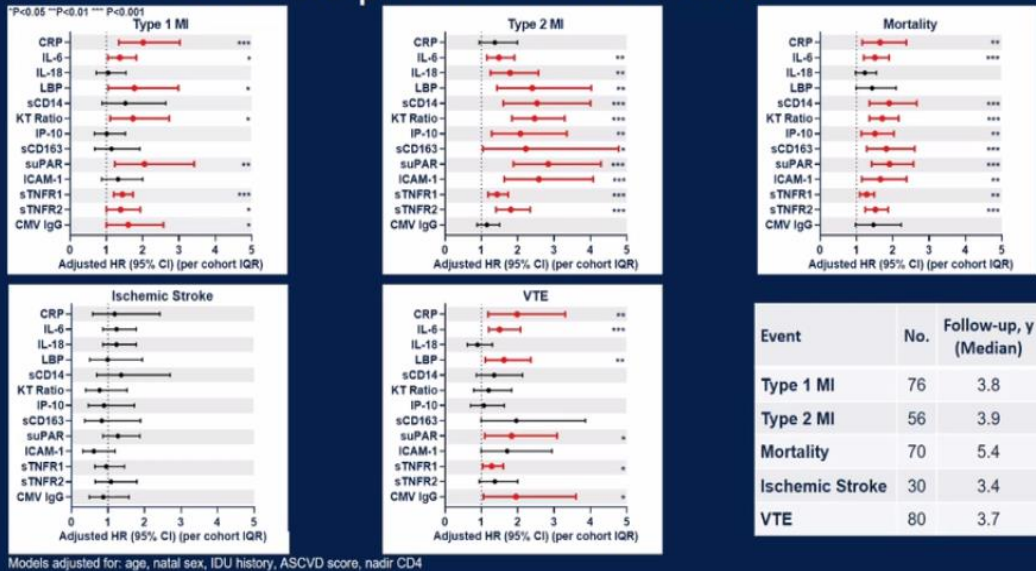

## Conclusions

- In the randomized controlled ES phase, comparison of change from Baseline to Week 48 in the DTG + RPV group vs the CAR group revealed no consistent patterns for inflammatory or atherogenesis biomarkers
- Longitudinally up to Week 148, no consistent pattern of change was observed after switch to DTG + RPV from CAR in
  - Inflammatory biomarkers: no change was observed in CRP, and the pattern of change was generally inconsistent across sCD14, IL-6, and sCD163
  - Atherogenesis biomarkers: FABP-2 and sVCAM-1 showed sustained reductions post-switch, and increases in D-dimer were inconsistent across both the ES and LS groups and across the 2 SWORD studies
- Overall, these results from SWORD-1 and SWORD-2 illustrate the lack of a consistent pattern of change in biomarkers post-switch to the 2DR DTG + RPV and hence provide no evidence for an association of increased inflammation or atherogenesis with the 2DR while maintaining virologic suppression

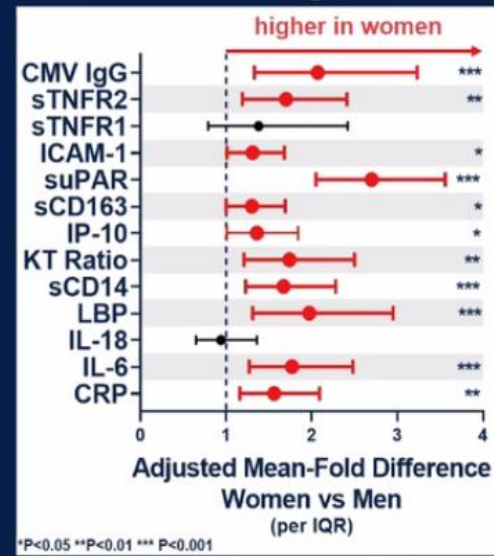

| Characteristics    | Median (IQR) or No. (%) |
|--------------------|-------------------------|
| Total participants | 979                     |

# Distinct biomarkers predict distinct events

# Women have higher levels of inflammation

Could this be hormone-mediated?  
 Median age in cohort: 47

Models adjusted for: age, natal sex, race/ethnicity, smoking, HCV, IDU history, ASCVD score, nadir CD4, CNICS site

# Sex may modify the inflammation-event association

The same increase in immune activation may more strongly predict events in women...

...but may be in a qualitatively different direction for VTE

Models adjusted for: ASCVD risk score

# **INSTIs**

- AUMENTO de PESO**
  - RIESGO CARDIOVASCULAR Y DM**
-

# CASE-BASED DISCUSSION ON WEIGHT GAIN IN HIV AND ANTIRETROVIRAL THERAPY

## PATOGENIA

- Multifactorial: genética, estilo de vida, dieta...
  - No todo es por el TARV
  - Mujer mas riesgo. Mas activación inmune?
- Retorno a la salud
  - Endocrina: *Negative energy balance* con el VIH –TARV repara el efecto negativo y recuperamos peso
- Aumento de apetito. Leptina (saciedad).
  - INSTI podrían actuar aquí? Poca evidencia
- Toxicidad mitocondrial de nuevo? (Dra. McComsey)
  - Biopsia grasa- toxicidad mitocondrial por TDF. Recuperación tras suprimir TDF. Estudios en marcha.
- Fibrosis en la grasa.
  - Inflamación puede relacionarse con fibrosis. Como en obesidad.

## TRATAMIENTO

- Cambio de tratamiento?
  - Estudio de *switch*. No optimista sobre volver a NNRTI y perder peso.
- Cambios en estilo de vida cuanto antes.

# PREDICTED 10-YEAR RISKS OF CARDIOVASCULAR DISEASE AND DIABETES IN THE ADVANCE TRIAL

Laura Hindley MPH

## Study Objective

- This analysis aimed to quantify the 10-year predicted risk of CVD and diabetes for ADVANCE participants using standard risk algorithms

### ADVANCE trial design (2017 – 2022)

**Inclusion criteria:** Treatment-naïve, HIV-1 RNA level > 500 copies/mL, no TB or pregnancy, no baseline genotyping

**Study visits:** Baseline, Weeks 4, 12, 24, 36, 48, 60, 72, 84, 96 then every 24 weeks to Week 192  
**Sample characteristics:** 99% black, 56% female, 62% South African

### Risk prediction analysis

- Body weight and laboratory measures from Week 144 were used to calculate the 10-year risk of CVD and T2D using the **QRISK**<sup>1</sup>, **Framingham**<sup>2</sup> (non-laboratory) and **QDiabetes**<sup>3</sup> risk algorithms
- Participants ≥30 years old at baseline included in analysis
- \*Most recent laboratory measure since Week 96 used when Week 144 measure was unavailable

10-year risk of developing:

| Risk equation Variables                     | Heart attack or stroke | Atherosclerotic CVD         | Type II diabetes |

Risk score given as median change (Q1, Q3) in score from baseline. Risk score gives 10-year risk (%) of developing an incident CVD or T2D event. P-values were derived from Mann-Whitney U tests comparing two different treatment groups. All participants ≥30 years old at baseline. The supplementary handout gives risk equation predictions by gender.

**1 additional heart attack or stroke** over 10 years per 1000 people treated with TAF/FTC+DTG vs TDF/FTC+EFV (p=0.016, QRISK)  
**7 additional diabetes cases** over 10 years per 1000 people treated with TAF/FTC+DTG vs TDF/FTC+DTG (p=0.024, QDiabetes)

Weight gain to week 144, participants ≥ 30 years\*

Changes in lab parameters to week 144, participants ≥ 30 years\*\*

# INCIDENT DIABETES ASSOCIATED WITH INTEGRASE STRAND TRANSFER INHIBITOR INITIATION

Jane O'Halloran

Washington University School of Medicine  
St. Louis, Missouri, USA

## Primary outcome

New diabetes mellitus or hyperglycemia in the six months post-ART initiation

## RESULTS

77% of people had a tenofovir disoproxil fumarate containing NRTI backbone

| Demographics        | INSTI   | No INSTI |
|---------------------|---------|----------|
| Mean Age (in years) | 42 (12) | 43 (10)  |
| Male sex            | 75%     | 80%      |
| Medicaid            | 21%     | 14%      |

2,836 (2.5%) event

➤ 93% new-onset diabetes mellitus, 7% hyperglycemia

Adjusted for age, male gender, Elixhauser co-morbidities, gestational diabetes, pancreatitis, pancreatitis malignancy, Hepatitis B & C, cardiovascular disease, hypoglycemia

### Limitations

- Administrative data may underestimate rates of hyperglycemia not yet clinically apparent
- Insufficient data to assess the impact of Tenofovir alafenamide

## CONCLUSIONS

Overall, those on INSTIs were 22% more likely to develop new-onset diabetes mellitus or hyperglycemia in the six months post index

The risk was more than twice as high in those on dolutegravir compared with those on elvitegravir, while raltegravir was not associated with this finding.

Although analysis on the impact of Tenofovir alafenamide was not performed, it is worth noting that there was almost no TAF use in those receiving dolutegravir

# RISK FACTORS FOR PROGRESSION FROM PREDIABETES TO DIABETES IN PERSONS WITH HIV

Mary Clare Masters, MD

Northwestern University Feinberg School of Medicine  
Chicago, IL, USA

## Study objective

To evaluate risk factors associated with progression from pre-DM to DM in a cohort of older PWH who have been largely virally suppressed and receiving modern ART

## Methods

### Study participants

- AIDS Clinical Trials Group (ACTG) A5322 (HAILO)
  - Ongoing, observational study at 32 U.S. sites
  - Initiated ART through an ACTG randomized clinical trial
  - Undergo annual fasting laboratory tests

### Definitions

- Pre-DM: fasting blood glucose (FBG) of 100-125 mg/dl
- DM: FBG $\geq$ 126 mg/dl, receiving medication treatment for diabetes, or clinical diagnosis

### Data analysis

- Proportional hazards Cox regression models to identify risk factors for development of DM among participants with pre-DM
- Factors associated with DM in univariable models (p-value  $<0.10$ ) were included in multivariable model

The A5322 (HAILO) Study

# Results

**1035 HAILO participants**

- 60 (6%) with DM at baseline
- 74 (7%) with pre-DM at baseline
- 679 (66%) developed pre-DM during follow-up

**Table 1. Participant characteristics at diagnosis of pre-DM**

| Characteristics                          | Total (N=753)      | Developed DM (N=167) |
|--|--------------------|----------------------|
| Age in years                             | 46 (41, 51)        | 45 (39, 50)          |
| Female sex                               | 121 (16.1%)        | 28 (16.8%)           |
| Race/ethnicity                           |                    |                      |
| Black, non-Hispanic                      | 214 (28.4%)        | 45 (26.9%)           |
| White, non-Hispanic                      | 376 (49.9%)        | 83 (49.7%)           |
| Other + Hispanic                         | 163 (21.6%)        | 39 (23.4%)           |
| HIV-1 RNA <50 (copies/ml)                | 552 (73.3%)        | 107 (64.1%)          |
| CD4 counts (cells/mm <sup>3</sup> ) >200 | 665 (88.3%)        | 132 (79.0%)          |
| BMI (kg/m <sup>2</sup> )                 | 26.6 (24.1, 30.5)  | 28.0 (24.6, 31.3)    |
| Waist circumference (cm)                 | 93.5 (86.0, 102.4) | 95.8 (88.7, 106.9)   |
| INSTI use                                | 93 (12.4%)         | 3 (1.8%)             |

**Table 2. Risk of DM in persons with pre-DM: Multivariable model**

| Variable                                 | HR   | 95% CI     | p-value |
|--|------|------------|---------|
| Clinical site region (ref=West)          |      |            |         |
| Northeast                                | 1.68 | 1.09, 2.61 | 0.02    |
| Midwest                                  | 1.40 | 0.91, 2.16 | 0.13    |
| South                                    | 1.19 | 0.72, 1.95 | 0.50    |
| HIV-1 RNA <50 (copies/ml)                | 0.95 | 0.68, 1.32 | 0.74    |
| CD4 counts (cells/mm <sup>3</sup> ) >200 | 0.55 | 0.37, 0.81 | <0.01   |
| INSTI use                                | 0.21 | 0.07, 0.67 | <0.01   |
| BMI, per 1-unit increase                 | 1.05 | 1.02, 1.08 | <0.01   |
| History of hypertension                  | 1.24 | 0.87, 1.77 | 0.24    |
| Family history of CVD                    | 0.83 | 0.53, 1.28 | 0.40    |

Of those on an INSTI, 67% were on raltegravir, 18% dolutegravir, 12% elvitegravir, and 3% bictegravir

- Median (IQR) time to DM was 45.3 weeks (18.7, 58.6)

- While INSTI use has been associated with weight gain and DM in other cohorts, its use was associated with a *lower* risk of progression to DM among HAILO participants.
- Higher CD4 was also associated with a lower risk of progression to DM, suggesting that immunosenescence as well as inflammation may be mediators in DM development among PWH with pre-DM.
- Further characterization of the metabolic effects associated with INSTI use and the effects of immune activation and inflammation on development of DM in PWH are needed.

# ASSOCIATION BETWEEN INTEGRASE STRAND TRANSFER INHIBITORS AND CARDIOVASCULAR DISEASE

Bastian Neesgaard on behalf of the RESPOND study group

CHIP, Dept. of Infectious Diseases Section 2100,  
Rigshospitalet, Copenhagen, Denmark

## Study objectives:

- To assess if exposure to INSTIs\* (raltegravir [RAL], elvitegravir [EVG/c] and dolutegravir [DTG]), is associated with an increased incidence of CVD.

## Methods:

### Inclusion:

- INSTI naïve RESPOND participants [1-2] aged ≥18 years, followed from latest of cohort enrolment or 1<sup>st</sup> of January 2012 (baseline)

### Outcomes:

- CVD - composite endpoint consisting of rigorously defined myocardial infarction (MI), strokes, and invasive cardiovascular procedures (ICP)

### Statistical analysis:

- Individuals were followed from baseline to the earliest of first CVD event, last follow-up or 1<sup>st</sup> of October 2018.
- Exposure to INSTIs was calculated following the methodology developed in D:A:D study. [3]
- Negative binomial regression models, adjusted for common CVD risk factors, HIV characteristics and ARVs previously associated with CVD - factors potentially associated with INSTI use and CVD were fixed at baseline.
- Logistic regression examined odds of starting an INSTI by D:A:D 5-year CVD risk score.

# Results:

- A total of **21,267** participants were included; **9,782 (46%)** exposed to an INSTI during follow-up. (6372 to DTG, 2385 to EVG/c and 2147 to RAL)
- Overall, **75.5% were white, 73.3% male, 48.9% of Western European origin and 41.2% MSM.**
- During a **median of 6.3 years** of follow-up (IQR 3.5-6.7; 106,870 PYFU); **517 CVD events (IR 4.9/1000 PYFU [CI 95%, 4.5-5.3])** of which, **210 MIs, 162 strokes and 145 ICPs.**
- Individuals experiencing CVD were older (**median, [IQR]: 53.7 [48.5-61.9] vs. 44.5 [36.2-51.5] years**), and a larger proportion had classic risk factors for CVD at baseline, than those without.
  - Greater proportion with a high/very high **5-year estimated D:A:D CVD risk score** in the group that experienced CVD (**46% vs 12%, P<0.001**).
- Odds ratio\*** [95%CI] of initiation INSTI by 5-year estimated D:A:D CVD risk, when compared to all compared to low risk (<1%):
  - Moderate risk (1 - <5%): **1.11 [1.00-1.21]**, high risk (5 - <10%): **1.19 [1.05-1.35]**, very high risk (>10%): **1.05 [0.89-1.25]**.

# Results:

**Figure A:**  
Crude incidence rates of CVD stratified by INSTI exposure

|                              |                  |                    |                  |                  |                  |                  |
|------------------------------|------------------|--------------------|------------------|------------------|------------------|------------------|
| Persons at risk (n)          | 21267            | 9454               | 8314             | 7289             | 5148             | 2931             |
| PYFU                         | 83237            | 5423               | 4327             | 6576             | 4132             | 3175             |
| Events (n)                   | 363              | 58                 | 24               | 43               | 17               | 12               |
| IR [95% Confidence interval] | 4.36 [3.92-4.83] | 10.70 [8.12-13.83] | 5.55 [3.55-8.25] | 6.54 [4.73-8.81] | 4.11 [2.40-6.59] | 3.78 [1.95-6.60] |

**Figure B:**  
Adjusted IR ratios of CVD stratified by INSTI exposure

## Conclusion:

- The INSTIs examined were associated with a **2.5 times greater incidence of CVD in the first 6 months of exposure** when compared to no INSTI exposure, after accounting for known CVD risk factors, and across a wide range of sensitivity analyses.
- These findings call for further investigations in mechanistic studies and other large populations of people living with HIV seen in routine clinical care.

# ENVEJECIMIENTO

---

- The objectives of this study were to assess the prevalence of frailty in PLHIV aged 70+, using the Fried phenotype index and to evaluate the association of frailty with HIV and non HIV-related factors.

## METHODS

SEPTAVIH ANRS EP66 study is a French, multicenter, prospective, observational study.

- Main Inclusion criteria: HIV-1 infection, aged 70 or older, ART treated for at least 12 months
- At baseline, we collected the following data:
  - Sociodemographic, clinical data and medical/HIV history
  - A comprehensive geriatric interview and examination assessing
    - history and risks of falls
    - associated medications
    - physical and cognitive function (MoCA)
    - mood disorders (CES-D questionnaire)
- Frailty was assessed using the 5 Fried frailty phenotype (FFP) criteria: recent spontaneous weight loss, low handgrip strength, exhaustion, slow walking speed, low physical activity.

PLHIV were categorized as **robust** (no criteria), **pre-frail** (1 or 2 criteria) and **frail** (> 2 criteria).

- We compared the frailty categories at baseline according to HIV parameters and socio-demographic factors (continuous variables with Kruskal-Wallis tests and categorical variables using Chi-2 tests).

## Characteristics of the Frailty phenotype in PLHIV 70+: the ANRS SEPTAVIH Study

From May 2019 to Jan 2020 510 PLHIV were included

- Age (med.) 73 years [IQR:71-77]
- Male 81.4 % (MSM 58.1 %)
- History of clinical AIDS 27.4%
- Known HIV duration (med.) 22.7 years
- Plasma HIV RNA <50 c/mL 95.3 %
- Baseline CD4 cell count (/mL) 562 [418-752]
- Non communicable comorbidities 3 [2-4]

Fried Frailty Phenotype

Distribution of the 5 Fried Frailty phenotype criteria in robust, prefrail and frail participants, %

## Factors associated with Frailty in PLHIV 70+: the ANRS SEPTAVIH Study

| % or median                      | Robust<br>n=111, 23.4% | Pre-frail<br>n=300, 63.1% | Frail<br>n=64, 13.5% | P-value |
|----------------------------------|------------------------|---------------------------|----------------------|---------|
| Age, years                       | 72                     | 73                        | 76                   | <0.001  |
| Male                             | 79.3                   | 82.3                      | 73.4                 | 0.85    |
| College education level          | 48.6                   | 36.3                      | 35.9                 | 0.02    |
| Homeowner                        | 70.3                   | 60.0                      | 45.3                 | 0.03    |
| Baseline CD4/mL                  | 623                    | 565                       | 498                  | 0.05    |
| Nadir CD4/mL                     | 185                    | 187                       | 155                  | 0.53    |
| HIV-RNA<50c/mL at baseline       | 96.4                   | 94.3                      | 85.9                 | 0.42    |
| Duration of HIV infection, years | 22.5                   | 22.8                      | 23.3                 | 0.84    |
| Comorbidities                    | 2                      | 3                         | 3                    | 0.04    |
| Deprived socioeconomic status    | 20.7                   | 32.7                      | 48.4                 | <0.001  |
| Cognitive impairment             | 44.1                   | 63.3                      | 60.9                 | <0.001  |

- In this population aged 70 or older, with a long duration of HIV infection, on ART and virologically suppressed, the prevalence of frailty was low, though nearly two thirds were prefrail.
- Socio-economic conditions, comorbidities and cognitive function were strongly associated with frailty, while HIV-related factors were not.
- These results suggest the need of targeted interventions in aging PLHIV to screen, prevent and manage frailty.

# COMORBILIDADES

---

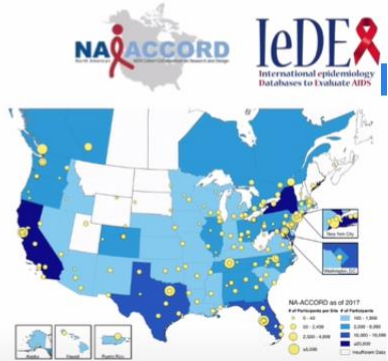

# Multimorbidity in people with HIV using ART in the United States: Projections to 2030

Parastu Kasaie, MS, PhD

The Johns Hopkins Bloomberg School of Public Health  
Baltimore, MD, USA

## PEARL unique characteristics

- Embraces the diversity of people with HIV
  - 5 gender and HIV acquisition risk groups \* 3 races and ethnicities = **15 subgroups**
- Leverages the breadth of the **CDC Surveillance** data, and the depth of the longitudinal **NA-ACCORD** data
- Simulating the US adult population age 15 to 85 **who have ever started ART**

### Projected burden of multimorbidity among people with HIV using ART in the US, 2009 – 2030

Population with  $\geq 2$  physical comorbidities in addition to HIV in:

**2020:**  
30% (678,000 persons)

**2030:**  
36% (929,000 persons)

~251,000 additional individuals living with  $\geq 2$  physical comorbidities

Hypertension, Hyperlipidemia, Diabetes, CKD, Cancer, MI & ESLD

## PEARL model

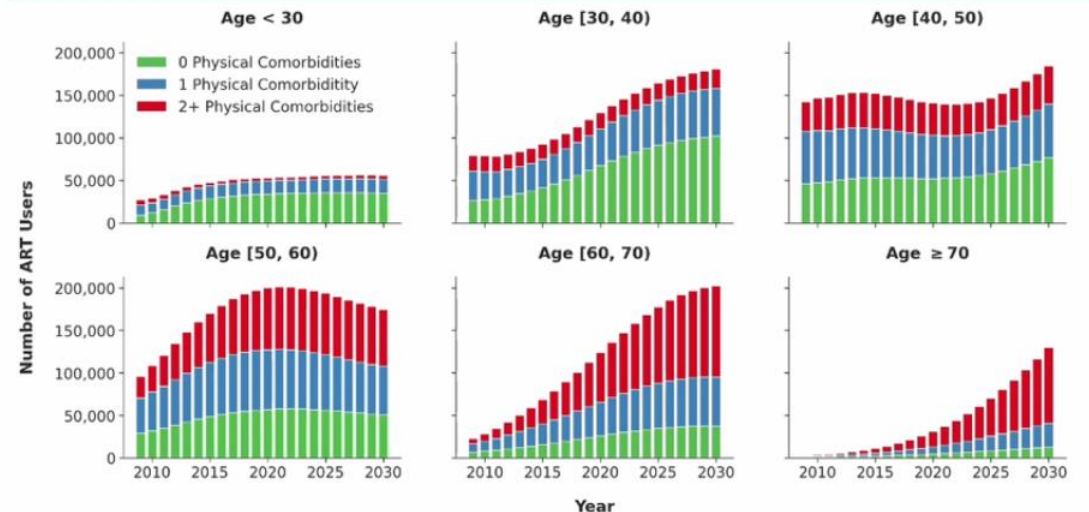

### ProjEcting Age, multimoRbidity, and poLypharmacy

## Results

- PEARL projects a substantial increase in number of ART users, reaching a population of 928,000 by 2030
- The overall median age increased from 50y in 2020 to 53y in 2030, with 25% of ART users  $\geq 65$ y in 2030

## Projected burden of multimorbidity by age

# Projected change in prevalence of comorbidities among people with HIV using ART in the US, 2020 – 2030

- Projected increase in prevalence of Anxiety, CKD, Depression, Diabetes & MI
- Projected slight reductions in prevalence of hyperlipidemia & hypertension
- Projected rise in cancer among male IDUs

## Patient Characteristics

20,256 PLWH were matched to 40,512 PLWoH

- 62% ≥50 years old  
Mean (SD): 52.3 (14.5) years
- 20.0% Female
- 45.9% White; 28.5% Black; 13.8% Hispanic
- 59.1% from South Region of US
- 65.4% Commercial insured  
34.6% Medicare Advantage

Table 1. Comorbidity Index Scores\*

| CCI score     | PLWH (n=20,256) | PLWoH (n=40,512) |
|---------------|-----------------|------------------|
| mean (SD)     | 0.9 (1.6)       | 0.6 (1.3)        |
| Categories, % |                 |                  |
| 0             | 61.3%           | 72.1%            |
| 1             | 14.1%           | 12.1%            |
| 2             | 12.0%           | 8.1%             |
| 3-4           | 8.1%            | 5.3%             |
| ≥5            | 4.5%            | 2.4%             |

| 60-69 yrs                                 | +0.66 | p<0.01 | +1.39 | p<0.01 |
| ≥70 yrs                                   | +0.62 | p=0.03 | +0.33 | p=0.46 |

†Unadjusted linear regression model including HIV, age, sex and all interaction terms in the model: HIV\*age p=0.0002, HIV\*sex p=0.3040, age\*sex p<0.0001, HIV\*age\*sex p=0.0014

**In the adjusted model†, findings were attenuated but HIV and age still significantly modified the estimated mean NACM burden by sex (HIV\*age\*sex, p=0.038)**

†Including covariates in the unadjusted linear regression model plus race, body mass index, smoking, drinking, cocaine, socioeconomic status

## CONCLUSIONS

- The prevalence and burden of NACM was high in the MWCCS among men and women with or at-risk for HIV
  - Particularly for hypertension, psychiatric illness, dyslipidemia, liver, and bone disease
- NACM burden was higher among women vs men, particularly among PWH, and varied by age category
  - The distribution of specific NACM prevalence differed by sex
- Given HIV is associated with differential effects on age-related comorbidities by sex, HIV serostatus- and sex-specific strategies for NACM screening and prevention are needed

**¡MUCHAS GRACIAS!**
